Classic Segmentation Scheme

Image in false colors \implies Extract feature(s) \implies

Segmentation according to the selected features

4 ∃ > 4

Challenges with Images

Example: Note that the objects of interest can be at different scales.

4 / 31

Challenges with Features

Depending on the choice of feature, results can vary.

How do you choose and represent a feature?

Vazquez (GMU)

SIAM 2017

Segmentation

There are many ways to do this, for example:

- Region Based
- Neural Networks
- Histogram
- Threshold
- Clustering
- Optimization
- etc.

Which method is best to segment according to the feature of interest?

通 ト イヨ ト イヨト

Our Proposed Scheme

Main Idea: Introduce manifold learning to achieve image segmentation

use manifold learning to cluster

Density Based Clustering

How would you cluster points with the following density f?

Challenges: (1) Points to be cluster are in m^2 dimensions. (2) We do not have access to the real density f, but an estimation \hat{f} .

Vazquez (GMU)

Cut: Super-level Set

Suppose we knew f, then a solution can be found looking at super-level sets, i.e. $\{x \in X_N : f(x) \ge \lambda\}$

Cluster: Connected Components

Connected components of $\{x \in X_N : f(x) \ge \lambda\}$

From patches to Pixels

Step 5: Label pixels using patch labels

To decide which cluster pixel (3,1) belongs to, we look at all the patches that it appears in. As illustrated in the top images, it only appears in 3 patches. The actual patches, shown on the bottom, were classified to cluster 1, 2, and 2, respectively. This means that cluster 2 gets 2 votes, and cluster 1 gets 1 vote. Therefore, this pixel gets placed in cluster 2.

Density Estimation

Our choice: $\hat{q}(x) = \frac{1}{||x-x_k||}$ i.e. one over the distance to the *k*th nearest neighbor (kNN).

Benefits of this estimator:

- Efficient algorithms to find $||x x_k||$
- Consistent with $q(x)^{\frac{1}{d}}$

Consistent Estimator

Suppose $X_N \subset \mathbb{R}^d$ is the set of data points, $x \in \mathbb{R}^d, x_i \in X_N$. Let $k \ge 1$ be fixed, x_i be identically distributed, and q be the density function. Also, suppose x_i is the *i*th nearest neighbor of x and define $\epsilon = ||x - x_k||$. Then:

$$\frac{k}{N} = \frac{1}{N} \sum_{i=1}^{N} \mathbb{1}_{\{d(x,x_i) \le \epsilon\}} \implies \mathbb{E}\left[\frac{k}{N}\right] = \mathbb{E}\left[\frac{1}{N} \sum_{i=1}^{N} \mathbb{1}_{\{d(x,x_i) \le \epsilon\}}\right]$$
$$\implies \frac{k}{N} = \frac{1}{N} \sum_{i=1}^{N} \mathbb{E}\left[\mathbb{1}_{\{d(x,x_i) \le \epsilon\}}\right] = \frac{c_1 \epsilon^d}{N} \sum_{i=1}^{N} (q(x) + \epsilon \mathcal{O}(\xi))$$
$$\implies \frac{k}{N} \propto \epsilon^d (q(x) + \mathcal{O}(\epsilon)) \implies ||x - x_k|| \propto q(x)^{-\frac{1}{d}} + \mathcal{O}(\epsilon)$$

Cluster

Our choice: Continuous k Nearest Neighbor (CkNN) introduced by T. Berry and T. Sauer.

Facts:

- It is a very efficient and accurate method of clustering
- The unnormalized graph Laplacian spectrally converges to the Laplace-de Rham operator
- This implies that the connected components of the CkNN graph will converge to the connected components of the manifold

Cluster

Comparing 5 different clustering algorithms.

Vazquez (GMU)

Classify

Our choice: kNN classifier, which is a very fast classifier but there could be better choices.

Steps

- I Find the k nearest neighbors that have a label
- Pick the most frequent label among the neighbors

Future Directions

- Better metrics to measure similarities between patches
- Hierarchical approach to achieve multiscale segmentation: How do we incorporate and compare different patch sizes?
- Find a sense of consistency for classifiers
